

Overview

In this lesson, you will build a **Trend Finder** tool that searches the internet for trending items based on any topic you enter.

For example, a user could search for:

- camping gear
- fitness gadgets
- kitchen tools
- photography accessories

The tool will search the internet and return the **Top 5 trending results** related to that topic.

Step 1 — Open Your Project in Visual Studio Code

- Open your project folder in **Visual Studio Code**.

Make sure the **Claude Code extension** is open so you can prompt Claude to generate the feature.

Step 2 — Create the Trend Finder Page

In the Claude prompt inside VS Code, ask Claude to do the following:

- Create a new navigation tab called **Trend Finder** and link it to a new page called **trend-finder.html**.

Make sure the new page follows the same styling as the rest of the website.

Step 3 — Ask Claude to Build the Trend Finder Tool

Next, ask Claude to build the Trend Finder system.

Requirements:

- The page should include a search input where a user can type any topic
- When the user searches, the system should find **trending items related to that topic from the internet**
- Show the **Top 5 results**

Each result should display:

- item or product name
- image if available
- source or store name
- a button that links to the original page

Important:

- Do not use fake sample data
- Use a Python backend with **Flask, requests, and BeautifulSoup**
- Create an API endpoint that returns trending results based on the user's search query
- Connect the frontend to the API so results appear automatically on the page

Generate all required files and explain where they should go.

Step 4 — Let Claude Generate the Code

Claude will now generate:

- the backend server
- the scraper
- the API
- the frontend search feature

Follow Claude's instructions and place the files in your project folder.

You do **not** need to write the code yourself.

Step 5 — Run the Project

Once Claude finishes generating the files, ask Claude how to run the project locally.

Typically, this will involve installing dependencies and starting the server.

Example commands:

```
pip install -r requirements.txt
```

```
python server.py
```

Then open your browser and visit:

<http://localhost:3000> (or wherever you are hosting)

Final Result

You will have a working **Trend Finder tool** that:

- lets users search any topic
- scans the internet for trending items
- shows the **Top 5 results** in a clean layout

This project demonstrates how AI tools like Claude can help you quickly build **powerful research and discovery tools** without writing every line of code yourself.
